Linux Productivity Tools

Ketan M. (km0@ornl.gov)

Oak Ridge National Laboratory

Enhanced version (originally presented at LISA19)

Table of Contents

Part 1: Overview and Logistics

orientation and practical stuff

Overview: What shall we learn

- Build powerful **command-lines**
  - We will use **Bash shell with default key-bindings**
  - We will **assume GNU/Linux** and call it Linux
- Tools that are available (or easily installable) on most installations
- Goal is to be efficient and effective rather than to be an "expert"
- Benefits: save time, efficient for system, long-term payback

- **We do not cover:** Sysadmin, Networking

Slides and practice data for download

- Slides and two text files available for practice

https://github.com/ketancmaheshwari/lisa19

- states.txt
  - Tabular data with five columns
- prose.txt
 - Prose with sentences and paragraphs

About You and Me

- Basic exposure to Linux is assumed but feel free to interrupt and ask questions
  - common commands, basic understanding of files and directories, editing etc.

- About Me
  - Linux Engineer at Oak Ridge National Laboratory
  - Command line enthusiast

part 2: Basics

welcome to the school of command line wizardry!

Anatomy of a Typical Command

options   command   argument

↓   ↓   ↓

`ls -lh /etc | grep 'conf'`

↑   ↑

command   pipe
Know the System

- **`id`**: know yourself
- **`w:`** who is logged in (**`-f`** to find where they are logging in from)
- **`lsblk`**: list block storage devices
- **`lscpu`**: display info about the CPUs
- **`lstopo`**: display hardware topology (need hwloc, hwloc-gui packages)
- **`free`**: free and used memory (try **`free -g`**)
- **`lsb_release`**: distribution info (try **`-a`**)

PS0: Use **`ctrl-c`** to kill stuck commands or long running ones

PS1: Some commands may not be available: **`which <cmdname>`** to verify

Know the Processes

- List the processes by name, pid etc: `ps` (commonly used flags: `aux`)
- `ps` implementations: POSIX, GNU and BSD!
  - implementations differ in behavior
  - determined by style of options: POSIX (-), GNU (--), BSD (no dash) before options
- Display processes: `top`, `htop`, `atop`
- Be `nice` and fly under the radar, eg.:
  - `nice -n 19 tar cvzf archive.tgz large_dir`
- Kill a process: `kill <pid>`
  - to kill zombie processes
  - hung sessions

Many ways to get help

- **`man nano`**
  - Manual pages
  - Organized section-wise -- one page for each section (if exists)
- **`wget --help`**
  - Handy for quick syntax reference
- **`info curl`**
  - Modern
- Browse **`/usr/share/doc`**
  - Usually a README file has info and examples
  - Browse with a web-browser

Working with Files

- **`cat`** for relatively short files
  `cat states.txt`
- **`less`** is more than **`more`** for long files
  `less /etc/ntp.conf`
- **`tail -f`** to watch a file growing live
- What can you do about binary files? (not much)
  - **`strings`** will print the printable strings of file
  - **`od`** will print file in octal format
  - **`cmp`** will compare them byte by byte
- Compare text files with
  - **`comm`** *sorted* files line by line
  - **`diff`** differences line by line -- used most frequently, rich options set, see man

Internet on command line

- **curl** is commonly used as command to download from the web:

  curl -O http://www.gutenberg.org/files/4300/4300-0.txt

  curl ifconfig.me #quickly find my IP

- **wget** is similar:

  wget http://www.gutenberg.org/files/4300/4300-0.txt

  wget https://kubernetespodcast.com/episodes/KPfGep{001..062}.mp3

- **lynx** can be a useful text-based browser:
  - avoid pesky ads on the web
  - when internet is slow / only care about text eg. **lynx text.npr.org**
  - read local html pages, eg. those found in **/usr/share/doc**
  - **w3m** and **links** are other text-based browsers: **w3m lite.cnn.com**

Be a command line ninja: Navigation

MAC users: terminal pref > profile > keyboard settings > Use option as meta key

`kubectl set subject rolebinding admin --user=ldf --group=nsed`

alt-b

alt-f

cursor

ctrl-a / ctrl-xx

ctrl-e

ctrl-] <char> moves cursor to 1st occurrence of <char> to right

ctrl-alt-] <char> moves cursor to 1st occurrence of <char> to left

Be a command line ninja: Deletion

```
kubectl get -o template pod/web-pod-13je7 --template={{.status.phase}}
```

ctrl-w

alt-d

cursor

ctrl-u

ctrl-k

use ctrl-y to paste back the deleted

wildcards: characters that expand at runtime

- **`* any number of characters:`**
  `ls -lh /etc/*.conf` `#all items with .conf extension`
- **`? expands to one character:`**
  `ls -ld ? ?? ???` `#list items 1,2 or 3 chars long`
- Negation (**`!`**)
  `ls -ld [!0-9]*` `#items that don't start with a number`

- Escaping and quoting
  - \ for escaping a wildcard ⎤
  - ' for quoting a wildcard ⎦ prevent expansion

Quick and Useful Tricks

- **!!** repeats the last command
- **!$** change command keep last argument:
  - **cat states.txt** # file too long to fit screen
  - **less !$** #reopen it with less
- **!*** change command keep all arguments:
  - **head states.txt | grep '^Al'** #should be tail
  - **tail !*** #no need to type the rest of the command

- **alt-.** #paste last argument of previous command
- **alt-<n>-alt-.** #paste **nth** argument of previous command

More Tricks

- **>x.txt** #create an empty file / "zero" a large file
- **cmd #tag** tag & search hard to remember command
- **ctrl-l** #clear terminal
- **cd -** #change to previous dir
- **cd** #change to homedir
- **ctrl-r** #recall from history
- **ctrl-d** #**logout** from terminal

Part 3: Streams, pipe and redirection

I am sure a gardener designed them!

Terminal I/O Streams and Redirection

- Three I/O streams on terminal:
standard input (**stdin**), standard output (**stdout**) and standard error (**stderr**)

- Represented by **"file descriptors"** (think of them as ids):
  - **0** for stdin, **1** for stdout, **2** for stderr

- Angle brackets are used for redirection to/from commands:
  - **>** to send to a stream
  - **<** to receive from a stream
  - **>>** to append to a stream
  - **<<** to in-place append (used in "heredoc")
  - **<<<** is used in "herestring" (not covering today)

- **&** is used to **"write into"** a stream, eg. **&1** to write into stdout

Anatomy of a redirection using streams

command

send

send

stderr

```
npm install -g tldr > out.txt 2 > err.txt
```

More Redirection Examples

- Send stdout and stderr to same file:
  ```
  pip install rtv > stdouterr.txt 2>&1
  ac -pd &> stdouterr.txt #short form (bash v4+)
  ```

- Disregard both stdout and stderr:
  ```
  wget imgs.xkcd.com/comics/command_line_fu.png &> /dev/null
  ```

- Read from stdin as output of a command
  ```
  diff <(ls dirA) <(ls dirB)
  ```

- Append stdout to a log file:
  ```
  sudo yum -y update >> yum_update.log
  ```

The pipe: run second command using output of first!

- A pipe is a Linux concept that automates redirecting the output of one command as input to a next command.

- Use of pipe leads to powerful combinations of independent commands. eg.:

find .| less #read long list of files page wise

head prose.txt | grep -i 'little'

echo $PATH | tr ':' '\n'#translate : to newline

history | tail #last 10 commands

free -m|grep Mem:|awk '{print $4}' #available memory

du -s *|sort -n|tail #10 biggest files/dirs in pwd

Demystifying and debugging piped commands

`free -m|grep Mem:|awk '{print $4}'`

is equivalent to running the following 4 commands:

`free -m > tmp1.txt`

`grep Mem: tmp1.txt > tmp2.txt`

`awk '{print $4}' tmp2.txt`

`rm tmp1.txt tmp2.txt`

Reducing the piped stages is often efficient and easier to debug. For instance, the above pipeline may be reduced like so:

`free -m|awk '/Mem:/{print $4}'` `#more on awk later`

More pipe examples

```
#get pdf of a man page
man -t diff | ps2pdf - diffhelp.pdf

#get today's files
ls -al --time-style=+%D | grep `date +%D`

#top 10 most frequently used commands
history | awk '{a[$2]++}END{for(i in a){print
a[i] " " i}}' | sort -rn | head
```

Commands that only accept literal args

- Most commands receive input from stdin (so, pipe) **and** file, eg.

  `wc < states.txt` #ok

  `wc states.txt` #ok

- There are some exceptions though

- Some receive input **only from stdin** and not from file, eg.
  - `tr 'N' 'n' states.txt` **#(strangely) NOT OK**
  - `tr 'N' 'n' < states.txt` #ok

- Some receive input **neither from stdin nor from file,** eg.
  - `echo < states.txt` **#NOT OK** (assuming want to print file contents)
  - `echo states.txt` **#NOT OK** (assuming want to print file contents)
  - `echo "Hello miss, howdy?"` #ok, takes literal args
  - `cp`, `touch`, `rm`, `chmod` are other examples

xargs: When pipe is not enough!

- Some commands do not read from standard input, pipe or file; they need arguments
- Additionally, some systems limit on number of arguments on command line
  - for example: **rm tmpdir/*.log** will fail if there are too many **.log** files
- **xargs** fixes both problems
  - Converts **standard input** to commands into **literal args**
  - Partitions the args to a permitted number and runs the command over them repeatedly
- For instance, create files with names on the **somelist.txt** file:
  xargs touch < somelist.txt

GNU Parallel

- Run tasks in parallel from command-line
- Similar to **`xargs`** in syntax
- Treats parameters as independent arguments to command and runs command on them in parallel
- Synchronized output -- as if commands were run sequentially
- Configurable number of parallel jobs
- Well suited to run simple commands or scripts on compute nodes to leverage multicore architectures
- May need to install as not available by default : www.gnu.org/software/parallel

GNU Parallel Examples*

- Find all html files and move them to a directory

```
find . -name '*.html' | parallel mv {} web/
```

- Delete pict0000.jpg to pict9999.jpg files (16 parallel jobs)

```
seq -w 0 9999 | parallel -j 16 rm pict{}.jpg
```

- Create thumbnails for all picture files (imagemagick software needed)

```
ls *.jpg | parallel convert -geometry 120 {} thumb_{}
```

- Download from a list of urls and report failed downloads

```
cat urlfile | parallel "wget {} 2>errors.txt"
```

*From the gnu parallel 2018 book at https://doi.org/10.5281/zenodo.1146014

Part 4: Classic Tools: find, grep, awk, sed

the evergreens

find: search files based on criteria

criteria (optional)

space

```
find /opt -name "README*" -exec wc -l {} +
```

path

action (optional)

Features of find

- **path**: may have multiple paths, eg. `find /usr /opt -iname "*.so"`
- **criteria**
  - -name, -iname, -type (f,d,l), -inum <n>
  - -user <uname>, -group <gname>, -perm (ugo+/-rwx)
  - -size +x[c], -empty, -newer <fname>
  - -atime +x, -amin +x, -mmin -x, -mtime -x
  - criteria may be combined with logical **and** (`-a`) and **or** (`-o`)
- **action**
  - `-print` : default action, display
  - `-ls` : run `ls -lids` command on each resulting file
  - `-exec cmd` : execute command
  - `-ok cmd` like exec except that command executed after user confirmation

find Examples

- **find . -type f -iname "*.txt"** #txt files in curdir
- **find . -maxdepth 1** #equivalent to ls
- **find ./somedir -type f -size +512M -print** #all files larger than 512M in ./somedir
- **find /usr/bin ! -type l** #**not** symlinks in /usr/bin
- **find $HOME -type f -atime +365 -exec rm {} +** #**delete** all files that were not accessed in a year
- **find . \(-name "*.c" -o -name "*.h" \)** #all files that have either .c or .h extension

grep: Search for patterns in text

- **grep** originally was a command "**g**lobal **r**egular **e**xpression **p**rint" or '**g/re/p**' in the **ed** text editor

- It was so useful that a separate utility called **grep** was developed

- **grep** will fetch **lines** from a text that has a match for a specific pattern

- Useful to find lines with a specific pattern in a large body of text, eg.:
  - look for a process in a list of processes
  - spot check a large number of files for occurrence of a pattern
  - exclude some text from a large body of text

Anatomy of grep

options

input file

```
grep -i -n 'col' states.txt
```

regular expression

Useful grep Options

- **-i**: ignore case
- **-n**: display line numbers along with lines
- **-v**: print inverse ie. lines that do not match the regular expression
- **-c**: print a count of lines of matches
- **-A<n>**: include n lines after the match
- **-B<n>**: include n lines before the match
- **-o**: print only the matched expression (not the whole line)
- **-E**: allows "extended" regular expressions that includes (more later)

Regular Expressions

- A regular expression (regex) is an **expression** that matches a **pattern**.
- Example pattern ....
  > ^Linux is fun.$
  > ^So is music.$
  > ^Traffic not so much.$

- regex: `b` `a` `r` ➔ no match
- regex: `f` `u` `n` ➔ **one** match ➔ "**Linux is fun.**"
- regex: `i` `s` ➔ **two** matches ➔ "**Linux is fun.**" and "**So is music.**"
- regex: `^` `S` `o` ➔ one match ➔ "**So is music.**"
- regex: `i` `c` `.` `$` ➔ one match ➔ "**So is music.**"

Regular Expressions-contd.

- **.** is a Special character; will match **any** character (except newline)
- Character class: one of the items in the **[ ]** will match, sequences allowed
  - **'[Cc]at'** will match **C**at and **c**at
  - **'[f-h]ate'** will match fate, gate, hate
  - **'b[^eo]at'** will match brat but **not** boat or beat
- **Extended** regular expressions (use with egrep or grep **-E**)
  - '*' matches zero or more, '+' matches one or more, '?' matches zero or one occurrence of the **previous character**
  - '|' is a delimiter for multiple patterns, '(' and ')' let you group patterns
  - {} may be used to specify a repetition range

grep Examples

- Lines that end with two vowels:
  grep '[aeiou][aeiou]$' prose.txt

- Check 5 lines before and after the line where term 'little' occurs:
  grep -A5 -B5 'little' prose.txt

- Comment commands and search later from history
  some -hard 'to' \remember --complex=command #success
  history | grep '#success'

- Confirm you got an ambiguous spelling right
  grep -E '^ambig(uou|ou|ouo)s$' /usr/share/dict/linux.words

- find+grep is one very useful combination
  find . -iname "*.py" -exec grep 'add[_-]item' {} +

awk: Extract **and** Manipulate Data

- A **programmable** filter that reads and processes input **line by line**

- Rich built-in features:
  - explicit fields ($1 ... $NF) & records management
  - functions (math, string manipulation, etc.)
  - regular expressions parsing and filtering

- Features like variables, loops, conditionals, associative arrays, user-defined functions

Highly recommended book: The awk programming language by Aho, Kernighan and Weinberger, ia802309.us.archive.org/25/items/pdfy-MgN0H1joIoDVoIC7/The_AWK_Programming_Language.pdf

Anatomy of an awk program

Often used as one-line **idiom** of the form:
```
        awk 'awk_prog' file.txt
```
OR
```
        command | awk 'awk_prog'
```

where **awk_prog** is:

```
BEGIN{actions} #run one time before input data is read

/pattern or condition/ {actions} #run for each line of input

END{actions} #run one time after input processing
```

At least one of the **BEGIN**, **/pattern or condition/**, **{}**, **END** section needed

awk patterns and actions

- A **pattern** is a regex that matches (or not) to an input line, eg.
  ```
  /New/                   # any line that contains 'New'
  /^[0-9]+ /              # beginning with numbers
  /(POST|PUT|DELETE)/ # has specific words
  ```

- An **action** is a sequence of ops, eg.
  ```
  {print $1, $NF}         #print first and last field/col
  {print log($2)}         #get log of second field/col
  {for (i=1;i<x;i++){sum += $3}} #get cumulative sum
  ```

- User defined functions may be defined in any action block

awk Examples

- awk **'{print $1}'** states.txt
- awk **'/New/{print $1}'** states.txt
- awk **NF > 0** prose.txt # print lines that has at least one field (skip blank lines)
- awk **'{print NF, $0}'** states.txt #fields in each line and the line
- awk **'{print length($0)}'** states.txt #chars in each line
- awk **'BEGIN**{print **substr("New York",5)**}' #York

sed: parse and transform text

- **sed** is a **s**tream **ed**itor
- Looks for a pattern in text and applies changes (edits) to them
- A batch or non-interactive editor
- Reads from file or stdin (so, pipes are good) **one line at a time**
- The original input file is unchanged (sed is also a filter), results are sent to standard output

- Most frequently used idiom is for text substitution

Anatomy of a typical sed command
Options

- address: may be a line number, range, or a match; default: whole file

- command: `s`:substitute, `p`:print, `d`:delete, `a`:append, `i`:insert, `q`:quit

- regex: A regular expression

- delimiter: Does not have to be `/`, can be `|` or `:` or any other character

- modifier: may be a number `n` which means apply the command to n[th] occurrence, `g` means apply globally in the line

- Common `sed` flags: `-n` (no print), `-e` (multiple ops), `-f` (read sed from file), `-i` (in place edit [careful])

Useful sed Examples

- **sed -n '5,9p' states.txt** #print lines 5 through 9
- **sed '20,30s|New|Old|1' states.txt** #affects 1st occurrence in ln20-30
- **sed -n '$p' states.txt** #print last line

- **sed '1,3d' states.txt** #delete first 3 lines
- **sed '/^$/d' states.txt** #delete all blank lines

- **sed '/York/!s/New/Old/' states.txt** #substitute except York

- **kubectl -n kube-system get configmap/kube-dns -o yaml | sed 's/8.8.8.8/1.1.1.1/' | kubectl replace -f -**

Part 5:
Session Management: tmux

for when the network goes down on my world-saving project

Workspace Management with tmux

- `tmux(v1.8)` is a terminal multiplexer that lets you create multiple, persistent terminals within one login

- In other words tmux is **a program which allows you to have persistent multiple "tabs" in a single terminal window**.

- Useful
  - when eg. a compilation or other operation will take a long time
  - for interactive multitasking
  - for exotic stuff such as pair programming

A Short tmux Tutorial

- Typical tmux workflow

```
tmux new -s mysession #start a new session
# run any commands as normal
ctrl-b :detach #detach the session, logout, go home
#later, log in again
tmux a -t mysession #get the same session back
```

- Other useful tmux commands

```
ctrl-b ( #switch to previous session
ctrl-b ) #switch to next session
tmux ls #list all sessions
tmux kill-session -t mysession #kill a session
```

Live collaboration with tmux

#user1#

tmux –S /tmp/collab

chmod 777 /tmp/collab

#user2#

tmux –S /tmp/collab attach

Create Panes and Synchronize with tmux

tmux #start a tmux session

ctrl-b " #split horizontally

ctrl-b % #split vertically

ctrl-b :setw synchronize-panes on
#synchronized#

ctrl-b :setw synchronize-panes off

ctrl-b o #move through the panes

ctrl-b x #kill the active pane

Part 6: ssh: config and tunneling

build secure tunnels

ssh config (~/.ssh/config)

```
Host login1
  hostname login1.ornl.gov
  User km0

Host cades
 Port 22
 hostname or-slurm-login.ornl.gov
 ProxyJump login1
 User km0
 ServerAliveCountMax=3 #max num of alive messages sent without ack
 ServerAliveInterval=15 #send a null message every 15 sec

# now to ssh/scp to cades, just need "ssh/scp cades"
```

Benefits of ssh config

- Makes ssh commands easier to remember in case of multiple hosts
- Customizes connection to individual hosts
- For more, see **`man 5 ssh_config`**
- For example: **`ssh summit`** is sufficient to connect to **`summit.olcf.ornl.gov`** with all the properties mentioned in the section:

```
Host summit
  Port 22
  hostname summit.olcf.ornl.gov
  User ketan2
  ServerAliveCountMax=3
  ServerAliveInterval=15
```

Port forward over SSH Tunnel*

local

"hostname" on remote host

remote
host

lclhost$ ssh -L lport:host:hport remotehost -N

ssh command

localport

port on remote host

no command

* simplest form

56

SSH Tunneling Example

- Run an HTTP server on remote node and browse through local web browser:

  step 1. **`remote$ python2 -m SimpleHTTPServer 25000`**
  OR
  step1. **`remote$ python3 -m http.server 25000`**

  step2. **`local$ ssh -L 8000:localhost:25000 id@remote -N`**

  step3. Open browser on **`local`** and navigate to http://**`localhost:8000`**

part 7: Secure Communication with GnuPG

Share top secrets securely over web

GNU Privacy Guard Basics

- A tool for secure communication

- We cover
  - keypair creation
  - key exchange and verification
  - encrypting and decrypting documents
  - authenticating documents with digital signatures

- We do not cover
  - public-key cryptography concepts
  - sophisticated and advanced use-cases

Create a new keypair

`gpg --gen-key` `#answer the prompted questions`
- Provide name and email as ID, choose hard-to-guess passphrase
- Keypair artefacts in `$HOME/.gnupg` dir

- Create a **revocation certificate**
  `gpg --output revoke.asc --gen-revoke <ID>`
- use the email as ID
- Useful to notify others the keypair may no longer be used -- eg. if you forgot your passphrase, lost keypair etc.

Key Exchange and Verification

- Export a public key
  gpg --output pub.gpg --export <ID> #binary
  gpg --armor --export > pubtxt.gpg #ascii

- Import a public key
  gpg --import billpub.gpg #import Bill's pubkey

- Verify and sign an imported key
  gpg --edit-key b@ms.us #out key info & prompt
  ...
  command> fpr #fingerprint, verify over phone
  command> sign #verify at prompt and done!

Encrypting and Decrypting Documents

- Encrypt a document for Bill using Bill's public key
  ```
  gpg --output doc_pdf.gpg --encrypt --recipient
  b@ms.us doc.pdf #must have Bill's public key
  ```
- Bill Decrypts the document (must have his private key & passphrase)
  ```
  gpg --output doc.pdf --decrypt doc_pdf.gpg
  ```

- Documents may be encrypted without key, just with passphrase
  ```
  gpg --output doc_pdf.gpg --symmetric doc.pdf
  Enter passphrase:
  ```

Authenticate Docs with Digital Signatures

- Digitally signed document ensure they are authentic & untempered
  `gpg --output doc.signed --sign doc.pdf`
  `Enter Passphrase:`
  Must have the private key to sign

- A signed document can be verified and decrypted like so:
  `gpg --ouput doc.pdf --decrypt doc.signed`
  Must have owner's public key

part 8: Bash Tools

For when that 'hello world' becomes a project

Bash Shell Basics

- Commands and utilities such as **`grep`**, **`sed`**, **`awk`** may be invoked

- Variables, constants, conditionals, loops and functions may be defined

- Arithmetic operations available

- Logical operations && (AND) and || (OR) available:
  - **`wget ...|| curl ...`** : run curl *iff* wget **fails**
  - **`make install && make test`** : test *iff* install **succeeds**

- Shell "Startup" files set environment as you start your shell
  - **`.bashrc`** : a file that runs in each new shell that is spawned
  - **`.bash_profile`** : a file that runs only in a "login shell" (and not all shells eg. it won't run if you invoke a shell script that creates a subshell)

Aliases and Functions

- Aliases are short and convenient names for long commands
- They are usually defined in .bashrc or a separate .aliases file
- To temporarily bypass an alias (say we aliased `ls` to `ls -a`), use \: `\ls`
- Bash functions are usually defined in `.bashrc/.bash_profile`
- Functions are more expressive and preferred over aliases

Examples of useful aliases

- **alias s=ssh**
- **alias c=clear**
- **alias cx='chmod +x'**
- **alias ls='ls -thor'**
- **alias more=less**
- **alias ps='ps auxf'**
- alias psg='ps aux | grep -v grep | grep -i -e USER -e'
- **alias ..='cd ..'**
- **alias myp='ps -fjH -u $USER'**
- **alias cleanup='rm -f *.tmp *.aux *.log'**

Examples of useful Functions

- **`mcd() { mkdir -p $1; cd $1 }`**
- **`cdl() { cd $1; ls}`**
- **`backup() { cp "$1"{,.bak};}`** `#test first`
- **`gfind() { find / -iname $@ 2>/dev/null }`**
- **`lfind() { find . -iname $@ 2>/dev/null }`**
- **`rtfm() { help $@ || man $@ || $BROWSER "http://www.google.com/search?q=$@"; }`**

- See **`/usr/share/doc/bash-*/examples/functions`** for more function examples

Variables and Command Substitution

- Variables are implicitly typed
- May be a literal value or **command substitute**
- **vname=value** #assign value to variable vname
- **$vname** #read value of variable vname

```
#!/bin/sh
msg="Hello World"
echo $msg
```

- Command substitution:
  - **curdir=$(pwd)**
  - **curdate=$(date +%F)**
  - **echo "There are $(ls -1 | wc -l) items in the current dir"**

Conditionals

- if-then-else construct to branch similar to programming languages
- Two forms of conditional evaluation mechanisms:
  - **test** and **[** … **]**

```
$ if test $USER = 'km0'; then echo 'I know you';
else echo 'Who are you'; fi

$ if [ -f /etc/yum.conf ]; then echo 'yum.conf
exists'; else echo 'file do not exist'; fi
```

Conditionals summary

- string
  - **-z string**: length of string 0
  - **-n string**: length of string not 0
  - **string1 = string2**: strings are identical (note a single =)
- numeric
  - **int1 -eq int2**: first int equal to second
  - **-ne, -gt, -ge, -lt, -le**: not-equal, greater-than, -greater-or-equal...
- file
  - **-r filename**: file exists and is readable
  - **-w filename**: file exists and is writable
  - **-f, -d, -s**: regular file, directory, exists and not empty
- logic
  - **!, -a, -o**: negate, logical and, logical or

Loops

- Basic structure (three forms):
  for i in {0..9}; do echo $i; done

  for ((i=0;i<10;i++)){ echo $i;} #C-like

  for var in list; do command; done #'python-like'

- often used with command substitution:
  for i in $(\ls -1 *.txt); do echo "$i"; done
  for i in $(get_files.sh); do upload.sh "$i"; done

The heredoc

- Create "inplace" files

- example:

- **sh << END
echo "Hello World"
END *<press enter>***

- Uses of heredoc
  - Multiline message using cat
  - Use variables to plug into created files, eg test multiple configurations for a program

```
cat << EOF | kubectl create -f -
apiVersion: v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
  - name: nginx
    image: nginx
EOF
```

```
#!/bin/bash
for i in local remote cluster all
do
  cat <<END>install.yml
  ---
  - hosts: $i
  <other stuff>
  END
  ansible-playbook install.yml --check > out"$i".txt
done
```

part 9: Program Development Tools

get-serious stuff

Programming Language Platforms

- Interpreted programming platforms available on most systems
  - Python - covered a bit
  - Perl - not covered
  - awk - covered some
  - Bash - covered some
- Compiled programming platforms available on most systems
  - C - cover some in this section
  - Fortran - not covered
- Additionally, a build system called `Make` is available

Elements of **C** Program Development

- The **source code** that is written/edited by a programmer
  - Often split into header files (`.h`) and source code files (`.c`)
- The compiler **gcc** does the following
  - compile (**-S** flag) convert the source code **(.c)** to **assembly code (.s)**
  - assemble (**-c** flag) -- translate the assembly code to **object code (.o)**
  - link (**-l** flag) -- link to the standard libraries to produce **executable**

- By default gcc combines the above stages producing the executable
  gcc hello.c #creates a.out; no .o or .s files

The **`make`** build system

- Automates compilation of multiple source files in a complex project

- Streamlines dependent actions and performs them in order

- Reads configuration from a "build" file usually named as Makefile

- Makefile acts as an artefact of project build process

Anatomy of a **Makefile**

target   dependencies

```
an_exe: main.o dep1.o dep2.o
        gcc -o an_exe main.o dep1.o dep2.o -lm
dep1.o: dep1.c
        gcc -c dep1.c
dep2.o: dep2.c
        gcc -c dep2.c
main.o: main.c
        gcc -c main.c
```

rules

must be a **tab**

command to achieve target

How the **make** command works

- The **make** command will read from the Makefile and run commands in order to build the ultimate target

- For instance, in the Makefile shown in previous slide, **make** will run commands for rule 2-4 followed by rule 1:
  gcc -c dep1.c #create dep1.o
  gcc -c dep2.c #create dep2.o
  gcc -c dep3.c #create dep3.o

  gcc -o an_exe dep1.o dep2.o dep3.o -lm

part 10: Miscellaneous Utilities

handy like midnight snack

Get things done at specific times with **at**

- **at** will execute the desired command on a specific day and time
  - **at 17:00 #press enter**
    at> log_days_activities.sh #smtimes no at> prompt
    [ctrl-d]
  - *at* offers keywords such as **now**, **noon**, **today**, **tomorrow**
  - offers terms such as **hours**, **days** to be used with the + symbol

    at noon
    at now + 1 year
   **at 3:08pm + 1 day**
    at 15:01 December 19, 2018

Get things done periodically with **cron**

- **cron** will execute the desired command periodically
- A **crontab** file controls and specifies what to execute when
- An entry may be created in any file and added to system with the **crontab** command like so:
  ```
  echo '15 18 30 6 * find /home -mtime +30 -print' > f00
  crontab f00 #add above to system crontab
  ```

- ```
  crontab -l #list crontab entries
  crontab -r #remove crontab entries
  ```

- Output of the cron'd command will be in **mail** (alternatively it may be redirected to a file with '>')
- What does the entries in a crontab mean though? (see next slide)

Anatomy of a crontab entry

command to be executed

hours (0-23)

month(Jan=1)

```
15  18  30  6  *  find /home -mtime +30 -print
```

mins (0-59)

day of month (0-max)

day of week (Sun=0)

Run the find command on June 30 of every year at 6:15 PM no matter what day of week it is.

Math

- Generate random number using **shuf** (may need to install)
  - **shuf -i 1-100 -n 1**
- Format numbers with **numfmt**
  - **numfmt --to=si 1000**
    1.0K
  - **numfmt --from=iec 1K**
    1024
- **bc** is a versatile calculator
  - **bc <<< 48+36** #no space on either side of +
  - **echo 'obase=16; ibase=10; 56'|bc** #decimal to hex
  - **echo 'scale=8; 60/7.02' |bc** #arbitrary precision

Python utilities

- Stand up a simple web server in under a minute with Python
  - `python3 -m http.server 35000`
- Pretty print a json file
  - `python3 -m json.tool afile.json`
- Run small python programs
  - `python -c "import math; print(str(math.pi)[:7])"`
- Do arithmetic
  - `python -c "print(6*6+20)"`
  - `python -c "fctrl=lambda x:0**x or x*fctrl(x-1); print(fctrl(6))"` #compute factorial

Random stuff - 1

- Run a command for specified time using **`timeout`**:
  `timeout 2 ping google.com`
- **`watch`** a changing variable
  - **`watch -n 5 free -m`**
- Say **`yes`** and save time
  - **`yes | pip install pkg --upgrade`**
  - **`yes "this is a test" | head -50 > testfile.txt`** `# create file with arbitrary no. of lines`
- Create pdf from text using **`vim`** :
  `vim states.txt -c "hardcopy > states.ps | q" && ps2pdf states.ps #convert ps to pdf`

Random stuff - 2

- Run a command as a different Linux group
  - **sg grpgit -c 'git push'**
- Display a csv in columnar/tabular format
  - **column -t -s , filename.csv**
- Have difficulty sending binary executables over emails?
  - **xxd f.exe f.hex** #hexdump the exe, send over email
  - **xxd -r f.hex f.exe** #receiver convert back to exe
- Generate password
  - **head /dev/urandom | tr -dc A-Za-z0-9 | head -c 8**
  - **openssl rand 8 -base64 | cut -c1-8** #-base64 8 for some version

Random stuff - 3

- Split a large file into small chunks (eg. to send as attachment in mail)
  - **split -b 20M large.tgz parts_** #20MB chunks
    #send parts_* over mail
  - **cat parts_a* > large.tgz** #at receiving end

Summary

- Linux command-line environment powerful if exploited well

- Pipes and redirection key Linux contributions

- Rewarding in the short-term as well as long-term

- Classical and modern tools well suited for modern-style usage

- Practice!

- Send comments, feedback, questions: `km0@ornl.gov`

Thank you for your time and attention
Questions?

Practice and Exercises

- Create three tmux sessions: s1, s2 and s3; detach them
- List the active sessions with **`tmux ls`**
- Kill the active sessions with **`tmux kill-session -t <name>`**
- Can you kill them all with one command? hint: use xargs in a pipe
- Create a tmux session and split the screen into 4 panes vertically and horizontally
- Set it so that all panes are synchronized. Test with any command.

Practice and Exercises

- Use your favorite editor to edit .bashrc and .bash_profile --
  - add a line: **`echo 'I am bashrc'`** to .bashrc
  - add a line: **`echo 'I am bash_profile'`** to .bash_profile
- Close and reopen terminal, what do you see? Within terminal type **`/bin/bash`**, what do you see?
- Create a copy of prose.txt using cp prose.txt tmp.txt; make small change to tmp.txt and compare prose.txt and tmp.txt with cmp, comm and diff
- Delete those lines from .bashrc and .bash_profile when done
- The character class **`[[:class:]] may be used as wild card`**: class may be alpha, alnum, ascii, digit, upper, lower, punct, word; try **`ls /etc/[[:upper:]]*`**

Practice and Exercises

- List all conf files in **/etc** you have access to, redirect stderr to **/dev/null**

- Build a software and collect errors and output in separate files, fill in the __
  make all __ std.out __ >std.err

- Run cmake command and gather all logs in a single file in background
  cmake .. __ __ cmake.log __ #bash v4 and above

- Same as above in long format
  mpirun -np 8 ./a.out __ outerr.txt 2>__1

Practice and Exercises

Simplify the following command line:

```
TOKEN=$(kubectl describe secret -n kube-system
$(kubectl get secrets -n kube-system | grep
default | cut -f1 -d ' ') | grep -E '^token' |
cut -f2 -d':' | tr -d '\t' | tr -d " ")
```

Hints:
- Replace the **cut** commands with **awk** commands
- Accommodate the **grep** within **awk**
- Accommodate the two **tr** commands within **awk** commands (hint: use **awk's gsub** built-in function)

Practice and Exercises

- Create a file titled the words that start with letter 'C' (**fill the __**):
  - **grep -i '^c' states.txt |awk '{print $4}'| __ touch**
- Remove temporary files:
  - **find . -iname '*.tmp' | __ rm #ok**
- Create a directory for all running processes
  - **ps | awk 'NR != 1 {print $4}'| mkdir #NOT OK**
  - **ps | awk 'NR != 1 {print $4}'| __ mkdir #ok**

Practice and Exercises

- Use **sed** to print lines 11-15 of states.txt
- Fill up the __ in the following find commands
  - `__ . -type d -perm 777 -exec chmod 755 {} +`
  - `find . -type __ -name "*.tmp" -exec rm -f {} +`
  - `find __ -atime +50` #files <50 days in /usr/local/lib
  - `find . -mtime __ -mtime -100` #<50 & <100 days
- Use **awk** to print only the state names and capitals columns from states.txt
- use **grep** to search for all lines of file states.txt containing a word of length four or more starting with the same two characters it is ending with. You may use extended regular expressions (**-E**)

Practice and Exercises

Muammar Gaddafi was a Libyan politician. He was in the news a few years ago. News agencies spelled his name differently like so:

- **`Muammar al-Kaddafi`** (BBC)
- **`Moammar Gadhafi`** (Associated Press)
- **`Muammar al-Qadhafi`** (Al-Jazeera)
- **`Mu'ammar Al-Qadhafi`** (US Department of State)

Your task is to come up with a Regular expression that will match with all the above occurrences. (Hint: use extended regular expression)

- Test with both **`grep`** and **`awk`** by putting the above lines in a file as well as a ***heredoc***

Practice and Exercises

- Compare the time it takes with and without the -C switch of scp to send data remotely (hint: use the `time` command)

- Create a config file in your ~/.ssh directory, make appropriate changes and add the contents presented in previous slides to it. How will you test if it works?

Practice and Exercises

- Run **yes** for 5 seconds using **timeout**

- Create an alias **d** to print current **date**

- Run **style** and **diction** (if available) on prose.txt

- Interpret the following crontab entry:
  ```
  30 21 * * * find /tmp /usr/tmp -atime +30 -exec rm -f {} +
  ```

- Frame an **at** command to run the date command tomorrow at 8 p.m.

- write a shell script to find all the prime numbers between 1000 and 10000
  - hints: use **for**, **if**, **factor**, **wc**
